

In this assignment, I explored some variation of the text with Oulipian N+7 technique (P+x). I used the Wallace Stevens' poem *The Snow Man*. Using GPT-2, each line's final word was replaced with the candidate token matching a specified probability rank derived from the model's logits.

Analyzing the generated outputs showed that changing x directly impacted token choices. High-ranking candidates often resulted in trailing word fragments? like *urn*, *urch*, or *vern* at x=7.

When increasing the parameter to x=40, the shift toward lower-probability candidate tokens introduced much more abstract and unpredictable fragments such as *idence*, *ural*, and *izz*. These lower-ranked tokens broke the logical flow of the original poem, producing surreal, absurd, and witty variations. Finding an ideal x required navigating between local syntactic coherence and chaotic unpredictability.

But to be honest, I think 7 is also nonsense.
